

## COS 214 Class Test 5 - L19 to L21

- This test takes place on 6th October 2020.
- The maximum duration of this test is 40 minutes.
- This test consists of **3 questions** for a total of **36 marks**.

Your client is currently using a financial system that makes use of XML to exchange data between components of their system. They have invested large quantities of money into this system and have a vast amount of data linked to this system which is stored in a data lake. Due to this investment, in the existing system, they are not ready to move over to a new system just yet. They have however purchased a system that will move them to the cutting edge again in terms of data analytics on the data they have in their data lake. This new system uses JSON to exchange data between its components.

Below is an architectural view of the systems and how they are to be adapted so that they can work together.

This is a UML Component diagram. The components (Financials, Analytics and Adaption) comprise of multiple classes. The lollipops (blue circles), represent the provided interface between components and the surrounding circle (socket), the required interface. XML and JSONAnalytics are classes defined within the Adaption component.

Effectively, communication can take place between the Finances component and the Analytics component and vice versa. We will only be considering communication from the Finances to the Analytics for the majority of the questions.

1.1 The classes that exist in the Adaption component are XMLInterface, XML, JSONInterface and (5) JSONAnalytics. XMLInterface and JSONInterface are both abstract classes.

Draw the UML Class diagram for the Object Adapter for this scenario. Show only the classes, whether they are abstract and the relationships between the classes. *Do NOT include any features* (functions and attributes)

(2)

1.2 Identify the corresponding classes for the participants of the Adapter design pattern. (3)

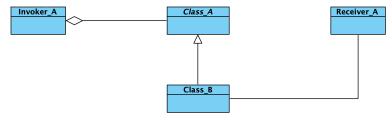

```
1.3 The JSONInterface class is given by: (5)
```

```
class JSONInterface {
  public:
    virtual string convert(string) = 0;
};
```

Provide a definition for the JSONAnalytics class.

## 

Rather than sending XML data from the Financials system to the Adaption system as text strings, you decide to send the data 'encapsulated' as a command. The following is an incomplete representation of the Command design pattern.

- 2.1 In which components will the classes representing the Invoker and Receiver participants of the (2) command pattern be defined?
- 2.2 Provide apt names, taking the scenario into account, for the classes labelled Class\_A and Class\_B. (2)
- 2.3 Which class, defined in Question 1, should have a relationship with Class\_B and what type of (2) relationship should this be?
- 2.4 If commands were to be sent from the Analytics component to the Adaption component, how (2) would the Command UML Class diagram given above change?
- 2.5 Propose a definition for Class\_A. (3)

## 

- 3.1 What is the main purpose of each of the following?
  - a) Doxygen
  - b) GitHub
- 3.2 The following section of a web page was generated using Doxygen. The code that was used to generate the page is the JSONInterface class definition.

### **Detailed Description**

The JSON Interface

#### Member Function Documentation

The decimal state sensitive state of the sensitive state of sensitive state state state state state of sensitive state of sensi

- a) How are multi-line comments specified in Doxygen? (1)
- b) Where do you think the text used to populate the *Detailed Description* section is placed in the (1) code file?
- c) What text on the web page was produced using a tag and what tag was it that was used to (2) produce the text?
- d) The return type of convert() is not shown in the documentation. How would you include it? (2)
- 3.3 What advantages does using a Git repository hold over not using one? (4)

# **COS 214 Class Test 5 – L19 to L21**

Student Number: u18050362

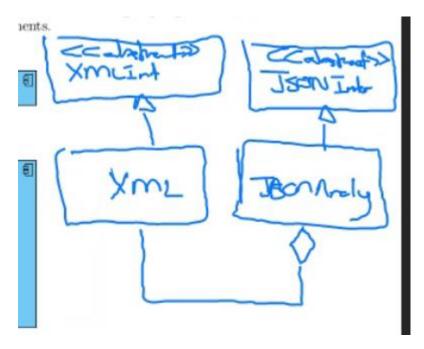

First Name: Werner Last Name: Graaff

Cell: 0716407441

Email: u18050362@tuks.co.za

# Question 1

### 1.1

```
Adapter: JSONAnalytics
Adaptee: XML
Target: JSONInterface
1.3
Class JSONAnalytics: public JSONInterface
{
    Public:
    JSONAnalytics();
    ~JSONAnalytics();
    JSONAnalytics(XML);
    Virtual string convert(string);
Private:
    XML* adapter;
}
```

# **Question 2**

2.1 Invoker: Financials Receiver: Adaption 2.2 Class A: Command Class\_B: XMLCommand 2.3 XMLInterface, xml should adhere to command 2.4 Add JSON command inheriting from class A 2.5 Virtual execute() = 0; **Question 3** 3.1 a) To generate documentation for programs in order to make them more understandable. 3.1 b) To enable teams to work together on large projects. 3.2 a) /\*\* Insert comment here \*/ 3.2 b) At the beginning of the JSON interface class definition.

3.2 c) "xmlString", the tag that was used is @param

### 3.2 d) By adding a @return tag

3.3 It enables you to have well documented version control, ensuring that everyone on the team are constantly working with the latest versions of the files. It makes it easy to determine which feature should be rolled back should it cause any problems with the rest of the code. GitHub also allows for branching, which makes it easier to work off of previous work if you found a better way to do something. It also allows you to easily track changes that was made by either yourself or other members of the team.
